# Outline

- 1 Motivation
- 2 Contributions
- 3 Basics of Disjunct matrices
- 4 Relation with Spark and Mutual Coherence
- 5 Recovery of Sparse Signals Using a Binary Matrix
  - Recovery of all sparse signals using Binary Matrix
  - Recovery of Almost All Sparse Signals Using a Binary Matrix
- 6 Disjunctness of a Sparse Matrix
- 7 Recovery of Sparse Signals Using a Sparse Matrix
  - Recovery of All Sparse Signals Using a Sparse Matrix
  - Recovery of almost all sparse signals using Sparse matrix
- 8 Simulation Results
  - Run-time Comparison
- 9 Future Work

## Motivation

- Basic pursuit (BP) & orthogonal matching pursuit (OMP): polynomial complexity in problem dimension
  - Impractical and expensive in high dimensional settings
- Verifying conditions based on spark and RIP is not easy
  - Hence, in practice, it remains unknown whether a given instantiation of the measurement matrix satisfies these properties

## Goal

Identify a property of a matrix that is easy to verify and also supports low computational complexity sparse recovery algorithms, while perhaps requiring a larger number of measurements for success.

## Contributions

- We connect non-adaptive group testing and compressed sensing
  - Disjunctness property of binary matrices is also very useful in recovering sparse signals
- We exploit the disjunctness property to present an ultra-low complexity algorithm for identifying the support as well as recover the nonzero coefficients of the sparse signal
  - Non-iterative algorithm, very fast
- We extend the disjunctness property of a binary matrix to sparse matrices. We show that a similar non-iterative and fast sparse recovery algorithm is possible

## Notation

- The set  $\{1, 2, \dots, n\}$  is denoted by  $[n]$ .
- The  $i$ -th entry of  $x$  is denoted by  $x_i$ .
- $\Phi(:, i)$  and  $\Phi(j, :)$  denote the  $i$ -th column and  $j$ -th row of  $\Phi$ , respectively, and  $\Phi(j, i)$  denotes the  $(j, i)$ th entry of  $\Phi$ .
- The support of  $x$  is  $\{i : x_i \neq 0\}$ , denoted by  $\text{supp}(x)$ .
- Let  $S \subset [n]$ , then  $x_S \triangleq (x_i)_{i \in S}$  and  $\Phi_S \triangleq (\Phi(:, i))_{i \in S}$

# Disjunct Matrix

## Definition 1

An  $m \times M$  binary matrix  $\Phi$  is called  $t$ -disjunct if the support of any column is not contained in the union of the supports of any other  $t$  columns.

Implications:

- If we take a submatrix  $\Phi_S$  with  $|S| = t + 1$ , then for  $i \in [t + 1]$ , there exists  $j_i$  such that  $\Phi_S(j_i, i) = 1$  and  $\Phi_S(j_i, l) = 0$  for all  $l \in [t + 1] \setminus i$
- This observation will be crucial for non-iterative recovery of almost all sparse signals

$t^e$ -disjunct Matrix

## Definition 2

A matrix  $\Phi$  is  $t^e$ -disjunct if, given any  $t + 1$  columns of  $\Phi$  with one designated column, there are  $e + 1$  rows with a 1 in the designated column and a 0 in each of the other  $t$  columns.

Implications:

- If we take a submatrix  $\Phi_S$  with  $|S| = t + 1$ , then for  $i \in [t + 1]$ , there exists  $j_i^1, \dots, j_i^{e+1}$  such that  $\Phi_S(j_i^d, i) = 1$  and  $\Phi_S(j_i^d, l) = 0$  for all  $l \in [t + 1] \setminus i$  and  $d = 1, \dots, e + 1$ .
- We exploit this property for recovering all signals with a given max. sparsity level

# Disjunctness of a Constant Column Weight Binary Matrix

## Theorem 1

Let  $\Phi$  be a  $m \times M$  matrix with each column containing  $q$  ones and the overlap (i.e., the size of the intersection of the supports) between any two distinct columns is at most  $r$ . Then  $\Phi$  is  $\lfloor \frac{q-1}{r} \rfloor$ -disjunct.

## Relation with Spark

### Definition 3

*The spark of a matrix is the smallest number of linearly dependent columns in the matrix*

- Necessary and sufficient condition for uniqueness
  - If  $\text{spark}(\Phi) = k$ , sparse vectors with up to  $k/2$  nonzero entries (and no more) can be uniquely recovered from  $y = \Phi x$

### Theorem 2

*The spark of a  $t$ -disjunct matrix is at least  $t + 1$*

### Proof 1

*Follows from the definition of a disjunct matrix.*

## Relation with Mutual Coherence

### Definition 4

The mutual coherence  $\mu_\Phi$  of  $\Phi$  is the maximum absolute inner product between any two distinct normalized columns of  $\Phi$

### Theorem 3

A matrix  $\Phi$  containing the same number of ones in each column is  $(\lfloor \mu_\Phi^{-1} \rfloor - 1)$ -disjunct.

### Proof 2

Follows from the fact that if each column of  $\Phi$  contains  $q$  ones and the overlap between any two columns is at most  $r$ , then its mutual coherence  $\mu_\Phi \leq \frac{r}{q}$ .

## Recovery of all sparse signals using Binary Matrix

- Suppose  $\Phi(:, i)$  contains  $q_i$  ones for  $i \in [M]$ ,  $q_{\min} \triangleq \min\{q_1, \dots, q_M\}$ , and that the overlap between any two distinct columns is at most  $r_{\max}$

### Theorem 4

$\Phi$  is  $t^e$ -disjunct for any  $t < \lfloor \frac{q_{\min}}{r_{\max}} \rfloor$  and  $e + 1 \geq q_{\min} - tr_{\max}$

### Theorem 5

Let  $\Phi$  be a binary matrix with every column containing at least  $q_{\min}$  ones and with the overlap between any two distinct columns at most  $r_{\max}$ . Then any  $\lfloor \frac{q_{\min}}{2r_{\max}} \rfloor$ -sparse vector can be uniquely recovered from  $y = \Phi x$

## Proof (and a fast recovery algorithm)

### Support recovery

$S = \{j : |\text{supp}(\Phi(:, i)) \cap \text{supp}(y)| > \frac{q_{\min}}{2}\}$  is the support of  $x$ .

### Non-zero coefficient recovery

**Step-1** : As  $\Phi$  is  $t^e$ -disjunct for some  $t < \lfloor \frac{q_{\min}}{r_{\max}} \rfloor$  and  $e \geq q_{\min} - tr_{\max} - 1$ , it is also  $\lfloor \frac{q_{\min}}{2r_{\max}} \rfloor^{\frac{q_{\min}}{2}}$ -disjunct.

**Step 2** : As a result, whenever  $s \in S$ , for  $\Phi_S(:, s)$  there exist  $j_s^1, \dots, j_s^{e+1}$  rows such that  $\Phi_S(j_s^d, s) = 1$  and  $\Phi_S(j_s^d, l) = 0$  for  $l \in S \setminus s$  and  $d = 1, \dots, e + 1$ .

**Step 3** : Thus, we can directly recover

$$x_s = \begin{cases} y_{j_s^d}, d = 1, \dots, e + 1 & \text{if } i \in S \\ 0, & \text{otherwise.} \end{cases} \quad (1)$$

# Recovery of Almost All Sparse Signals Using a $t$ -Disjunct Binary Matrix

- **Assumption** :  $y_j = \sum_{l \in \text{supp}(\Phi_S(j, :))} x_l \neq 0, \forall j \in [m]$
- This holds (a) with probability 1 if  $x$  is drawn from a generic random model; and (or?) (b)  $x$  is a non negative sparse signal

## Support recovery

$$S = [M] \setminus \bigcup_{j: y_j=0} \text{supp}(\Phi(j, :))$$

## Non-zero coefficient recovery

**Step-1** : As  $\Phi$  is  $t$ -disjunct, for  $i \in [k]$ , there exists  $j_i$  such that  $\Phi_S(j_i, i) = 1$  and  $\Phi_S(j_i, l) = 0$  for all  $l \in [k] \setminus i$

**Step 2** : Set

$$x_i = \begin{cases} y_{j_i}, & \text{if } i \in S \\ 0, & \text{otherwise} \end{cases} \quad (2)$$

# Disjunctness of a Sparse Matrix

## Definition 5

An  $m \times M$  sparse matrix  $\Phi$  is said to be  $t$ -disjunct if the support of any column is not contained in the union of the supports of any  $t$  other columns

- Let  $\Phi$  be a sparse matrix where  $\Phi(:, i)$  contains  $q_i$  non-zeros for  $i \in [M]$  with  $q_{\min} \triangleq \min\{q_1, \dots, q_M\}$
- Let the cardinality of the intersection between support of any two distinct columns be at most  $r_{\max}$

## Theorem 6

$\Phi$  is  $t^e$ -disjunct if  $t < \lfloor \frac{q_{\min}}{r_{\max}} \rfloor$  and  $e + 1 \geq q_{\min} - tr_{\max}$ .

## Recovery of All Sparse Signals Using a Sparse Matrix

- Consider the linear system  $y = \Phi x$ , where  $k < \frac{q_{\min}}{2r_{\max}}$

### Support recovery

$$S = \{j : |\text{supp}(\Phi(:, i)) \cap \text{supp}(y)| > \frac{q_{\min}}{2}\}.$$

### Non-zero coefficient recovery

(Step 1) and (Step 2): same as the binary case

Step 3: Set

$$x_s = \begin{cases} \frac{y_{j_s^d}}{\Phi_S(j_s^d, s)}, & d = 1, \dots, e + 1 \quad \text{if } i \in S \\ 0, & \text{otherwise} \end{cases} \quad (3)$$

## Recovery of almost all sparse signals using Sparse matrix

- **Assumption** :  $y_j = \sum_{l \in \text{supp}(\Phi_S(j,:))} \Phi(j, l)x_l \neq 0, \forall j \in [m]$ .
- This holds for same conditions as given for binary matrices.
- Consider the linear system  $y = \Phi x$ , where  $\Phi$  is  $t$ -disjunct and  $k < t + 1$ .

### Support recovery

$$S = \{i : \text{supp}(\Phi(:, i)) \subseteq \text{supp}(y)\}$$

### Non-zero coefficient recovery

**Step 1:** same as in binary case.

**Step 2:** Now set

$$x_i = \begin{cases} \frac{y_j}{\Phi(j,i)}, & \text{if } i \in S \\ 0, & \text{otherwise.} \end{cases} \quad (4)$$

## Simulation Results

- We use the binary sensing matrix  $\Phi$  of size  $q^2 \times q^{r+1}$  constructed by Devore<sup>4</sup> for  $q$  being prime power and  $r > 1$ .
- Every column of  $\Phi$  has  $q$  ones and the overlap between any two distinct columns is at most  $r$
- $\Phi$  is  $\lfloor \frac{q-1}{r} \rfloor$ -disjunct and  $t^e$ -disjunct with  $t < \lfloor \frac{q}{r} \rfloor$  and  $e + 1 \geq q - tr$
- As an example, we take  $\Phi$  of size  $(29)^2 \times (29)^3$ . Therefore,  $\Phi$  is 14-disjunct and also  $7^{14}$ -disjunct (i.e.,  $t = 7, e = 14$ ) and  $\mu_\Phi \leq \frac{2}{29}$

## Continued ...

- We consider sparsity  $k \leq 33$ . For each  $k$ , we generate 1000 random  $k$ -sparse vectors
- Our algorithm recovers sparse vectors with  $k = 15$  in all 1000 trials, as expected
- Further, the algorithm can recover  $x$  with much higher sparsity, up to  $k = 33$ , in all 1000 trials
- An existing non-iterative sparse recovery algorithm<sup>5</sup> can recover the unknown sparse vector  $x$  only up to sparsity 7 exactly in all 1000 trials. Beyond  $k = 9$ , it fails to recover even a single unknown sparse vector
- This is because the existing algorithm requires  $4k < q$ , i.e.,  $k < 8$ , in order to ensure that each nonzero entry in  $x$  occurs at least  $q/2$  times in  $y$ .

# Run-time Comparison

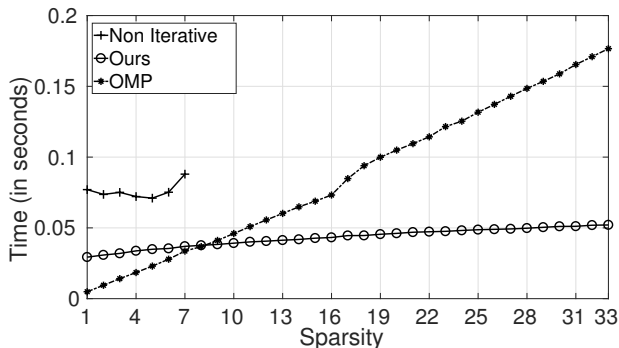

Figure: Average runtime comparison between Our proposed method, OMP and the existing non-iterative algorithm for matrix size  $(29)^2 \times (29)^3$

## Future Work

- Deriving bounds on the number of rows required for the measurement matrix to satisfy  $t$ -disjunctness
- Sparse signal recovery guarantees for disjunct matrices in noisy measurement settings.

THANK YOU!
