# Recap: Search with Noise for a Stationary Target

- Ulam-Rényi game: a noisy channel is introduced to model the behavior of the responder who can lie to decline to answer queries

# Recap: Search with Noise for a Stationary Target

- Ulam-Rényi game: a noisy channel is introduced to model the behavior of the responder who can lie to decline to answer queries
- Target: estimate a random variable  $S$  with unknown distribution

# Recap: Search with Noise for a Stationary Target

- Ulam-Rényi game: a noisy channel is introduced to model the behavior of the responder who can lie to decline to answer queries
- Target: estimate a random variable  $S$  with unknown distribution
- Task: design queries and decoder (scheme/strategy/procedure)

# Recap: Search with Noise for a Stationary Target

- Ulam-Rényi game: a noisy channel is introduced to model the behavior of the responder who can lie to decline to answer queries
- Target: estimate a random variable  $S$  with unknown distribution
- Task: design queries and decoder (scheme/strategy/procedure)
- Motivation: diverse applications including
  - medical diagnosis, chemical triage, human-in-the-loop decision-making
  - fault-tolerant communications, beamforming design in millimeter wave communication
  - target localization with a sensor network, object localization in an image

# Adaptive and Non-Adaptive Query Schemes

- A query asks whether  $S$  lies in a certain set  $\mathcal{A} \subset [0, 1]$

# Adaptive and Non-Adaptive Query Schemes

- A query asks whether  $S$  lies in a certain set  $\mathcal{A} \subset [0, 1]$
- Query schemes can be classified as adaptive and non-adaptive

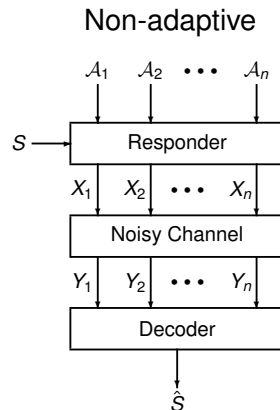

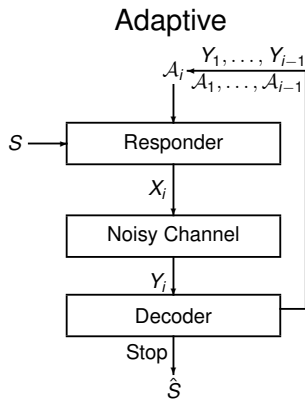

# Adaptive and Non-Adaptive Query Schemes

- A query asks whether  $S$  lies in a certain set  $\mathcal{A} \subset [0, 1]$
- Query schemes can be classified as adaptive and non-adaptive

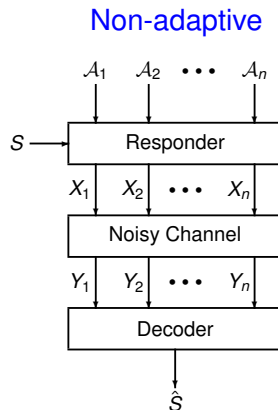

# Adaptive and Non-Adaptive Query Schemes

- A query asks whether  $S$  lies in a certain set  $\mathcal{A} \subset [0, 1]$
- Query schemes can be classified as adaptive and non-adaptive

# Adaptive and Non-Adaptive Query Schemes

- A query asks whether  $S$  lies in a certain set  $\mathcal{A} \subset [0, 1]$
- Query schemes can be classified as adaptive and non-adaptive

# Measurement-Dependent<sup>1</sup> Noise Model

- Given a query (measurement)  $\mathcal{A}$ , a responder's noiseless answer is corrupted by measurement-dependent noise via  $P_{Y|X}^{\mathcal{A}}$ .

<sup>1</sup>Y. Kaspi, O. Shayevitz, and T. Javidi, "Searching with measurement dependent noise," IEEE Trans. Inf. Theory, vol. 64, no. 4, pp. 2690-2705, 2018.

# Measurement-Dependent<sup>1</sup> Noise Model

- Given a query (measurement)  $\mathcal{A}$ , a responder's noiseless answer is corrupted by measurement-dependent noise via  $P_{Y|X}^{\mathcal{A}}$ .
- The channel  $P_{Y|X}^{\mathcal{A}}$  depends on the query  $\mathcal{A}$  only through a bounded Lipschitz continuous function  $f : [0, 1] \rightarrow \mathcal{R}$  of its size  $|\mathcal{A}|$ .

<sup>1</sup>Y. Kaspi, O. Shayevitz, and T. Javidi, "Searching with measurement dependent noise," IEEE Trans. Inf. Theory, vol. 64, no. 4, pp. 2690-2705, 2018.

# Measurement-Dependent<sup>1</sup> Noise Model

- Given a query (measurement)  $\mathcal{A}$ , a responder's noiseless answer is corrupted by measurement-dependent noise via  $P_{Y|X}^{\mathcal{A}}$ .
- The channel  $P_{Y|X}^{\mathcal{A}}$  depends on the query  $\mathcal{A}$  only through a bounded Lipschitz continuous function  $f : [0, 1] \rightarrow \mathcal{R}$  of its size  $|\mathcal{A}|$ .
- For any  $(q_1, q_2) \in [0, 1]^2$ ,  $|f(q_1) - f(q_2)| \leq \mu|q_1 - q_2|$ .

<sup>1</sup>Y. Kaspi, O. Shayevitz, and T. Javidi, "Searching with measurement dependent noise," IEEE Trans. Inf. Theory, vol. 64, no. 4, pp. 2690-2705, 2018.

# Measurement-Dependent<sup>1</sup> Noise Model

- Given a query (measurement)  $\mathcal{A}$ , a responder's noiseless answer is corrupted by measurement-dependent noise via  $P_{Y|X}^{\mathcal{A}}$ .
- The channel  $P_{Y|X}^{\mathcal{A}}$  depends on the query  $\mathcal{A}$  only through a bounded Lipschitz continuous function  $f : [0, 1] \rightarrow \mathcal{R}$  of its size  $|\mathcal{A}|$ .
- For any  $(q_1, q_2) \in [0, 1]^2$ ,  $|f(q_1) - f(q_2)| \leq \mu|q_1 - q_2|$ .
- When  $f$  is a constant value function, the noise model reduces to a measurement-independent model.

<sup>1</sup>Y. Kaspi, O. Shayevitz, and T. Javidi, "Searching with measurement dependent noise," IEEE Trans. Inf. Theory, vol. 64, no. 4, pp. 2690-2705, 2018.

# Problem Formulation: Search for a Multidimensional Moving Target

- Target: estimate the trajectory of a  $d$ -dimensional moving target with initial location  $\mathbf{S} = (S_1, \dots, S_d) \in [0, 1]^2$  and moving velocity  $\mathbf{V} = [V_1, \dots, V_d] \in [-v_+, v_+]^d$

# Problem Formulation: Search for a Multidimensional Moving Target

- Target: estimate the trajectory of a  $d$ -dimensional moving target with initial location  $\mathbf{S} = (S_1, \dots, S_d) \in [0, 1]^d$  and moving velocity  $\mathbf{V} = [V_1, \dots, V_d] \in [-v_+, v_+]^d$
- Task: design queries and a decoder for accurate estimation
  - Both  $\mathbf{S}$  and  $\mathbf{V}$  are **unknown** to the questioner
  - The joint distribution  $f_{\mathbf{S}\mathbf{V}}$  of  $(\mathbf{S}, \mathbf{V})$  is **arbitrary and unknown**

# Problem Formulation: Search for a Multidimensional Moving Target

- Target: estimate the trajectory of a  $d$ -dimensional moving target with initial location  $\mathbf{S} = (S_1, \dots, S_d) \in [0, 1]^d$  and moving velocity  $\mathbf{V} = [V_1, \dots, V_d] \in [-v_+, v_+]^d$
- Task: design queries and a decoder for accurate estimation
  - Both  $\mathbf{S}$  and  $\mathbf{V}$  are **unknown** to the questioner
  - The joint distribution  $f_{\mathbf{S}\mathbf{V}}$  of  $(\mathbf{S}, \mathbf{V})$  is **arbitrary and unknown**
- Assumption: the responder knows both  $\mathbf{S}$  and  $\mathbf{V}$   $\rightarrow$  real time locations of the target

# Problem Formulation: Search for a Multidimensional Moving Target

- Target: estimate the trajectory of a  $d$ -dimensional moving target with initial location  $\mathbf{S} = (S_1, \dots, S_d) \in [0, 1]^d$  and moving velocity  $\mathbf{V} = [V_1, \dots, V_d] \in [-v_+, v_+]^d$
- Task: design queries and a decoder for accurate estimation
  - Both  $\mathbf{S}$  and  $\mathbf{V}$  are **unknown** to the questioner
  - The joint distribution  $f_{\mathbf{S}\mathbf{V}}$  of  $(\mathbf{S}, \mathbf{V})$  is **arbitrary and unknown**
- Assumption: the responder knows both  $\mathbf{S}$  and  $\mathbf{V}$   $\rightarrow$  real time locations of the target
- Applications: search for a moving target (e.g., a car, wild animals, missing airplane) using sensor networks or satellites

# The Torus model for the Moving Target

Given initial location  $\mathbf{s} = (s_1, \dots, s_d)$  and moving velocity  $\mathbf{v} = (v_1, \dots, v_d)$ , at each time  $t \in \mathbb{R}_+$ , the real time location of the target at  $i$ -th dimension satisfies:

$$l(s_i, v_i, t) := \begin{cases} 1 & \text{if } \text{mod}(s_i + tv_i, 2) = 1, \\ s_i + tv_i - \lfloor s_i + tv_i \rfloor & \text{if } s_i + tv_i \in \bigcup_{h \in \mathbb{N}} [2h, 2h + 1), \\ \lceil s_i + tv_i \rceil - (s_i + tv_i) & \text{otherwise,} \end{cases}$$

# Definition of Non-Adaptive Query Procedures

Given any  $(n, d) \in \mathbb{N}^2$ ,  $\delta \in \mathbb{R}_+$  and  $\varepsilon \in [0, 1)$ , a  $(n, d, \delta, \varepsilon)$ -non-adaptive query procedure consists of

- $n$  queries  $\mathcal{A}^n$  where at time  $i$ , questioner asks whether the moving target's current location lies in set  $\mathcal{A}_i \subset [0, 1]^d$
- and a decoder  $g : \mathcal{Y}^n \rightarrow [0, 1]^d \times \mathcal{V}^d$  such that the worst-case excess-resolution probability satisfies

$$P_e(n, d, \delta) := \sup_{f_{sv}} \Pr \left\{ \max_{t \in [0:n]} \|l(\hat{\mathbf{S}}, \hat{\mathbf{V}}, t) - l(\mathbf{S}, \mathbf{V}, t)\|_\infty > \delta \right\} \leq \varepsilon.$$

# Definition of Non-Adaptive Query Procedures

Given any  $(n, d) \in \mathbb{N}^2$ ,  $\delta \in \mathbb{R}_+$  and  $\varepsilon \in [0, 1)$ , a  $(n, d, \delta, \varepsilon)$ -non-adaptive query procedure consists of

- $n$  queries  $\mathcal{A}^n$  where at time  $i$ , questioner asks whether the moving target's current location lies in set  $\mathcal{A}_i \subset [0, 1]^d$
- and a decoder  $g : \mathcal{Y}^n \rightarrow [0, 1]^d \times \mathcal{V}^d$  such that the worst-case excess-resolution probability satisfies

$$P_e(n, d, \delta) := \sup_{f_{sv}} \Pr \left\{ \max_{t \in [0:n]} \|l(\hat{\mathbf{S}}, \hat{\mathbf{V}}, t) - l(\mathbf{S}, \mathbf{V}, t)\|_\infty > \delta \right\} \leq \varepsilon.$$

- 
- Accurate estimation of the trajectory implies accurate estimation of  $(\mathbf{S}, \mathbf{V})$  and vice versa

# Definition of Non-Adaptive Query Procedures

Given any  $(n, d) \in \mathbb{N}^2$ ,  $\delta \in \mathbb{R}_+$  and  $\varepsilon \in [0, 1)$ , a  $(n, d, \delta, \varepsilon)$ -non-adaptive query procedure consists of

- $n$  queries  $\mathcal{A}^n$  where at time  $i$ , questioner asks whether the moving target's current location lies in set  $\mathcal{A}_i \subset [0, 1]^d$
- and a decoder  $g : \mathcal{Y}^n \rightarrow [0, 1]^d \times \mathcal{V}^d$  such that the worst-case excess-resolution probability satisfies

$$P_e(n, d, \delta) := \sup_{f_{sv}} \Pr \left\{ \max_{t \in [0:n]} \|l(\hat{\mathbf{S}}, \hat{\mathbf{V}}, t) - l(\mathbf{S}, \mathbf{V}, t)\|_\infty > \delta \right\} \leq \varepsilon.$$

- 
- Accurate estimation of the trajectory implies accurate estimation of  $(\mathbf{S}, \mathbf{V})$  and vice versa
    - Excess-resolution event occurs if  $|\hat{S}_i - S_i| > \delta$  or  $n|\hat{V}_i - V_i| > 2\delta$  for some dimension  $i \in [d]$

# Definition of Non-Adaptive Query Procedures

Given any  $(n, d) \in \mathbb{N}^2$ ,  $\delta \in \mathbb{R}_+$  and  $\varepsilon \in [0, 1)$ , a  $(n, d, \delta, \varepsilon)$ -non-adaptive query procedure consists of

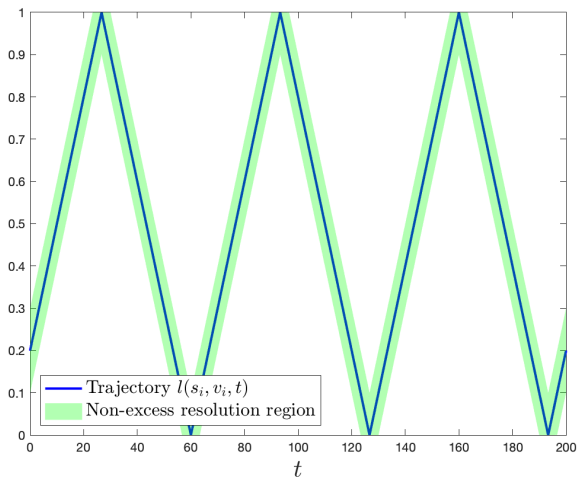

- $n$  queries  $\mathcal{A}^n$  where at time  $i$ , questioner asks whether the moving target's current location lies in set  $\mathcal{A}_i \subset [0, 1]^d$
- and a decoder  $g : \mathcal{Y}^n \rightarrow [0, 1]^d \times \mathcal{V}^d$  such that the worst-case excess-resolution probability satisfies

$$P_e(n, d, \delta) := \sup_{f_{sv}} \Pr \left\{ \max_{t \in [0:n]} \|l(\hat{\mathbf{S}}, \hat{\mathbf{V}}, t) - l(\mathbf{S}, \mathbf{V}, t)\|_\infty > \delta \right\} \leq \varepsilon.$$

- 
- Accurate estimation of the trajectory implies accurate estimation of  $(\mathbf{S}, \mathbf{V})$  and vice versa
    - Excess-resolution event occurs if  $|\hat{S}_i - S_i| > \delta$  or  $n|\hat{V}_i - V_i| > 2\delta$  for some dimension  $i \in [d]$
    - Excess-resolution event won't occur if  $|\hat{S}_i - S_i| \leq \alpha\delta$  and  $n|\hat{V}_i - V_i| \leq (1 - \alpha)\delta$  for all dimensions  $i \in [d]$

# Explanation of the Non-Excess Resolution Event

For each  $i \in [d]$ , the  $i$ -th dimension does *not* incur excess-resolution if the estimated trajectories are within  $\delta$  around the true trajectory at each time (in green shaded region).

# Excess-Resolution Case 1: Wrong Estimate of Initial Location

If the initial location  $s_j$  is estimated wrongly such that  $|\hat{s}_j - s_j| > \delta$ , then an excess-resolution event occurs.

## Excess-Resolution Case 2: Wrong Estimate of the Velocity

If the velocity  $v_i$  is estimated wrongly such that  $n|\hat{v}_i - v_i| > 2\delta$ , then an excess-resolution event occurs.

# Excess-Resolution Case 3: Wrong Estimate of Both

If both the location  $s_i$  and the velocity  $v_i$  are estimated wrongly, an excess-resolution event occurs.

# Excess-Resolution Event and the Number of Queries

Longer search time  $n$  requires more accurate estimation of the initial location and the velocity

- Given any number of queries  $n \in \mathbb{N}$  and  $\varepsilon \in [0, 1]$ ,

$$\delta^*(n, d, \varepsilon) := \inf\{\delta \in \mathbb{R}_+ : \exists \text{ an } (n, d, \delta, \varepsilon)\text{-non-adaptive query procedure}\}.$$

- Given any number of queries  $n \in \mathbb{N}$  and  $\varepsilon \in [0, 1]$ ,

$$\delta^*(n, d, \varepsilon) := \inf\{\delta \in \mathbb{R}_+ : \exists \text{ an } (n, d, \delta, \varepsilon)\text{-non-adaptive query procedure}\}.$$

- minimal resolution** achievable by any non-adaptive query procedure with  $n$  queries and excess-resolution probability  $\varepsilon$

- Given any number of queries  $n \in \mathbb{N}$  and  $\varepsilon \in [0, 1]$ ,

$$\delta^*(n, d, \varepsilon) := \inf\{\delta \in \mathbb{R}_+ : \exists \text{ an } (n, d, \delta, \varepsilon)\text{-non-adaptive query procedure}\}.$$

- minimal resolution** achievable by any non-adaptive query procedure with  $n$  queries and excess-resolution probability  $\varepsilon$
- finitely many query** performance is more practical than asymptotic analysis with infinite number of queries

- Given any number of queries  $n \in \mathbb{N}$  and  $\varepsilon \in [0, 1]$ ,

$$\delta^*(n, d, \varepsilon) := \inf\{\delta \in \mathbb{R}_+ : \exists \text{ an } (n, d, \delta, \varepsilon)\text{-non-adaptive query procedure}\}.$$

- minimal resolution** achievable by any non-adaptive query procedure with  $n$  queries and excess-resolution probability  $\varepsilon$
- finitely many query** performance is more practical than asymptotic analysis with infinite number of queries
- Dual quantity (sample complexity):

$$n^*(d, \delta, \varepsilon) = \inf\{n \in \mathbb{N} : \delta^*(n, d, \varepsilon) \leq \delta\}$$

## Theorem 1

For any  $\varepsilon \in (0, 1)$  and  $d \in \mathbb{N}$ , the minimal achievable resolution  $\delta^*(n, d, \varepsilon)$  satisfies

- if  $nv_+ = O(n^t)$  for  $t \in [0.5, 1)$ ,

$$-2d \log \delta^*(n, d, \varepsilon) = nC + O(nv_+);$$

- if  $nv_+ = O(n^t)$  for  $t \in [0, 0.5)$

$$-2d \log \delta^*(n, d, \varepsilon) = nC + \sqrt{nV_\varepsilon} \Phi^{-1}(\varepsilon) + O(\max\{nv_+, \log n\});$$

# Characterization of the Minimal Achievable Resolution $\delta^*(n, d, \varepsilon)$

## Theorem 1

For any  $\varepsilon \in (0, 1)$  and  $d \in \mathbb{N}$ , the minimal achievable resolution  $\delta^*(n, d, \varepsilon)$  satisfies

- if  $nv_+ = O(n^t)$  for  $t \in [0.5, 1)$ ,

$$-2d \log \delta^*(n, d, \varepsilon) = nC + O(nv_+);$$

- if  $nv_+ = O(n^t)$  for  $t \in [0, 0.5)$

$$-2d \log \delta^*(n, d, \varepsilon) = nC + \sqrt{nV_\varepsilon} \Phi^{-1}(\varepsilon) + O(\max\{nv_+, \log n\});$$

- Provides tight approximation to the performance of optimal non-adaptive queries

# Characterization of the Minimal Achievable Resolution $\delta^*(n, d, \varepsilon)$

## Theorem 1

For any  $\varepsilon \in (0, 1)$  and  $d \in \mathbb{N}$ , the minimal achievable resolution  $\delta^*(n, d, \varepsilon)$  satisfies

- if  $nv_+ = O(n^t)$  for  $t \in [0.5, 1)$ ,

$$-2d \log \delta^*(n, d, \varepsilon) = nC + O(nv_+);$$

- if  $nv_+ = O(n^t)$  for  $t \in [0, 0.5)$

$$-2d \log \delta^*(n, d, \varepsilon) = nC + \sqrt{nV_\varepsilon} \Phi^{-1}(\varepsilon) + O(\max\{nv_+, \log n\});$$

- Provides tight approximation to the performance of optimal non-adaptive queries
- The two assumptions on maximal speed  $v_+$  specify two regimes
  - Regime 1: # queries is greater than  $O(1/v_+^2)$  (fast target,  $v_+ = O(\frac{1}{\sqrt{n}})$  and  $v_+ = o(1)$ )

# Characterization of the Minimal Achievable Resolution $\delta^*(n, d, \varepsilon)$

## Theorem 1

For any  $\varepsilon \in (0, 1)$  and  $d \in \mathbb{N}$ , the minimal achievable resolution  $\delta^*(n, d, \varepsilon)$  satisfies

- if  $nv_+ = O(n^t)$  for  $t \in [0.5, 1)$ ,

$$-2d \log \delta^*(n, d, \varepsilon) = nC + O(nv_+);$$

- if  $nv_+ = O(n^t)$  for  $t \in [0, 0.5)$

$$-2d \log \delta^*(n, d, \varepsilon) = nC + \sqrt{nV_\varepsilon} \Phi^{-1}(\varepsilon) + O(\max\{nv_+, \log n\});$$

- Provides tight approximation to the performance of optimal non-adaptive queries
- The two assumptions on maximal speed  $v_+$  specify two regimes
  - Regime 1: # queries is greater than  $O(1/v_+^2)$  (fast target,  $v_+ = O(\frac{1}{\sqrt{n}})$  and  $v_+ = o(1)$ )
  - Regime 2: # queries is fewer than  $O(1/v_+^2)$  (slow target,  $v_+ = o(\frac{1}{\sqrt{n}})$ )

# Characterization of the Minimal Achievable Resolution $\delta^*(n, d, \varepsilon)$

## Theorem 1

For any  $\varepsilon \in (0, 1)$  and  $d \in \mathbb{N}$ , the minimal achievable resolution  $\delta^*(n, d, \varepsilon)$  satisfies

- if  $nv_+ = O(n^t)$  for  $t \in [0.5, 1)$ ,

$$-2d \log \delta^*(n, d, \varepsilon) = nC + O(nv_+);$$

- if  $nv_+ = O(n^t)$  for  $t \in [0, 0.5)$

$$-2d \log \delta^*(n, d, \varepsilon) = nC + \sqrt{nV_\varepsilon} \Phi^{-1}(\varepsilon) + O(\max\{nv_+, \log n\});$$

- Provides tight approximation to the performance of optimal non-adaptive queries
- The two assumptions on maximal speed  $v_+$  specify two regimes
  - Regime 1: # queries is greater than  $O(1/v_+^2)$  (fast target,  $v_+ = O(\frac{1}{\sqrt{n}})$  and  $v_+ = o(1)$ )
  - Regime 2: # queries is fewer than  $O(1/v_+^2)$  (slow target,  $v_+ = o(\frac{1}{\sqrt{n}})$ )
- In Regime 2, the first-order asymptotic result is *not* sufficient (see next slide)

# First- and Second-order Asymptotics for the Resolution Decay Rate

- First-order asymptotics: the asymptotic resolution decay rate

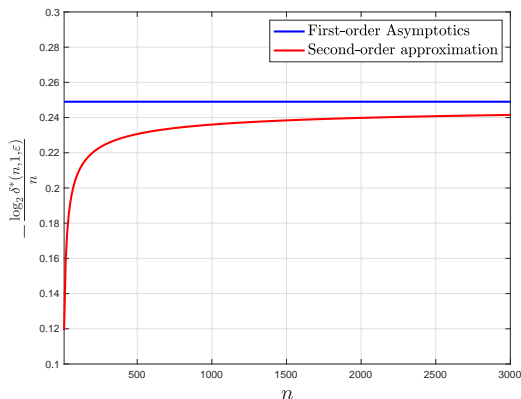

$$\lim_{n \rightarrow \infty} \frac{-\log \delta^*(n, d, \varepsilon)}{n} = \frac{C}{2d}$$

# First- and Second-order Asymptotics for the Resolution Decay Rate

- First-order asymptotics: the asymptotic resolution decay rate

$$\lim_{n \rightarrow \infty} \frac{-\log \delta^*(n, d, \varepsilon)}{n} = \frac{C}{2d}$$

- Second-order asymptotics: characterize the backoff from first-order ( $nv_+ = o(\sqrt{n})$ )

- Refines the result by Kaspi *et al.*, TIT 2018 (Theorem 3):
  - Second-order asymptotic, non-vanishing vs first-order asymptotic, vanishing
  - Any measurement dependent channel vs a measurement dependent BSC
  - Multidimensional vs one-dimensional

- Refines the result by Kaspi *et al.*, TIT 2018 (Theorem 3):
  - Second-order asymptotic, non-vanishing vs first-order asymptotic, vanishing
  - Any measurement dependent channel vs a measurement dependent BSC
  - Multidimensional vs one-dimensional
- Consistent with intuition that searching for a moving  $d$ -dimensional target is roughly equivalent to searching for a  $2d$ -dimensional target
  - Analysis is totally **different**: account for all trajectories and twist of location and velocity
  - Much more **complicated**: time complexity is  $O(n^{2d+1} v_+^d M^{2d})$  to search for a moving target v.s.  $O(nM^{2d})$  to search for a stationary target when the target resolution is  $\frac{1}{M}$

# An Important Implication: Phase Transition

- Minimal excess-resolution probability  $\varepsilon^*(n, d, \delta)$  when  $nv_+ = o(\sqrt{n})$

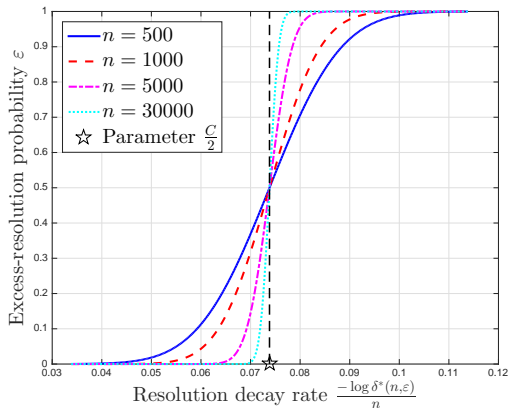

$$\varepsilon^*(n, d, \delta) = \Phi\left(\frac{-d \log \delta - nC}{\sqrt{nV_\varepsilon}}\right) + o(1)$$

# An Important Implication: Phase Transition

- Minimal excess-resolution probability  $\varepsilon^*(n, d, \delta)$  when  $nv_+ = o(\sqrt{n})$

$$\varepsilon^*(n, d, \delta) = \Phi\left(\frac{-d \log \delta - nC}{\sqrt{nV_\varepsilon}}\right) + o(1)$$

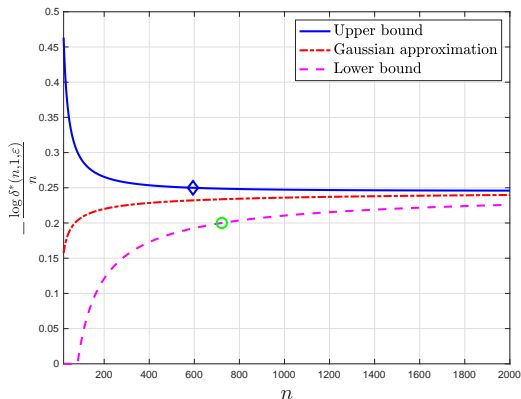

- BSC with crossover probability  $(2|\mathcal{A}| + 0.5) \times 0.2$

# The Impact of the Maximal Speed for A One-Dimensional Target

- Consider uniformly distributed location  $S \in [0, 1]$  and velocity  $V \in [-v_+, v_+]$
- Consider BSC with crossover probability  $(|\mathcal{A}| + 0.5) \times 0.05$  and set  $\varepsilon = 0.1$ .
- Gaussian approximation (Second-order asymptotic approximation)

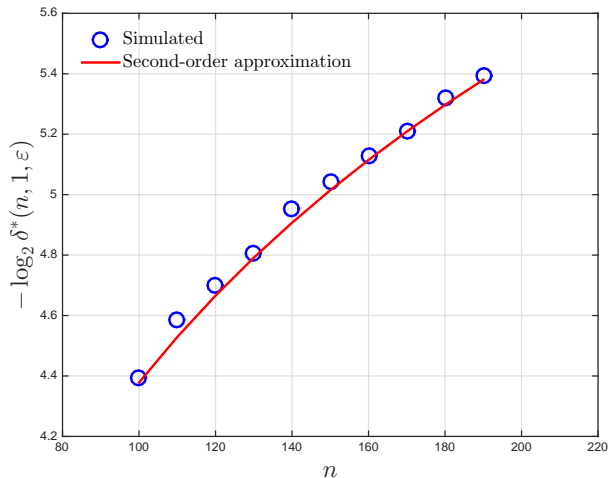

(a)  $v_+ = \frac{1}{n}$

(b)  $v_+ = \frac{\log n}{n}$

# Numerical Simulation

- $nv_+ = 0.1$
- $10^4$  independent trials for each  $n$

- Searching for a moving target with unknown initial location and velocity
