# Converting RLBWT to LZ77 in smaller space 

Kyushu Institute of Technology
Masaki Shigekuni \& Tomohiro I

## Background

- Various lossless compression methods have been proposed to efficiently process large-scale data
- Each compression method has its advantages and disadvantages, so it would be nice to be able to convert the compression format as needed

RLBWT: Compression method suited for compressed string indexes
LZ77: Dictionary-based compression achieving a high compression rate

- A one-pass algorithm of converting from RLBWT to LZ77 in compressed space has been proposed by [Nishimoto \& Tabei, 2019]
- In this study, we propose a two-pass algorithm that reduces its peak memory usage

## Suffix array

- The suffix array (SA) of T is a list of text positions sorted in the lexicographic order of suffixes starting at their positions

$T=$| 1 | 2 | 3 | 4 | 5 | 6 |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $a$ | $b$ | $c$ | $a$ | $b$ | $\$$ |

| Suffixes |
| ---: |
| $\mathrm{abcab} \$$ |
| $\mathrm{bcab} \$$ |
| $\mathrm{cab} \$$ |
| $\mathrm{ab} \$$ |
| $\mathrm{~b} \$$ |
| $\$$ |

| SA <br> position | SA | Sorted <br> suffixes |
| :---: | :---: | :--- |
| 1 | 6 | $\$$ |
| 2 | 4 | ab\$ |
| 3 | 1 | abcab\$ |
| 4 | 5 | b\$ |
| 5 | 2 | bcab\$ |
| 6 | 3 | cab $\$$ |

## Burrows-Wheeler Transform (BWT)

- BWT is a permutation of characters of T
- BWT $[i]=T[S A[i]-1]$ if SA[i] > 1, otherwise BWT[i] = \$
- BWT of a highly repetitive string can be compressed greatly by run-length encoding
- Run-length encoded BWT is called RLBWT

| Suffixes |
| ---: |
| abcab\$ |
| $\mathrm{bcab} \$$ |
| $\mathrm{cab} \$$ |
| $\mathrm{ab} \$$ |
| $\mathrm{~b} \$$ |
| $\$$ |$\quad$| BWT | SA | Sorted <br> suffixes |
| :--- | :--- | :--- |
| b | 6 | $\$$ |
| c | 4 | $\mathrm{ab} \$$ |
| $\$$ | 1 | $\mathrm{abcab} \$$ |
| a | 5 | $\mathrm{~b} \$$ |
| a | 2 | $\mathrm{bcab} \$$ |
| b | 3 | $\mathrm{cab} \$$ |

BWT of "abcab\$"
RLBWT

## Lempel-Ziv 77 (LZ77)

- Parse a string greedily into phrases from right-to-left such that each phrase consists of the longest substring that appears to the right plus one character
- The $h$-th phrase is encoded by a triplet $\left(\pi_{h}, \lambda_{h}, \mathrm{c}_{h}\right)$, representing $\mathrm{c}_{h} T\left[\pi_{h} . . \pi_{h}+\lambda_{h}-1\right]$

$$
T=\left\lvert\, \begin{array}{lllllllllllll}
1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13
\end{array} 14\right.
$$

## Backward search

- The maximum interval prefixed with a string $w$ is called w-interval
- The process of computing cw-interval from w-interval for a character c is called backward search

| SA <br> position | SA | Sorted suffixes |
| :---: | :---: | :--- |
| 1 | 6 | $\$$ |
| 2 | 4 | ab\$ |
| 3 | 1 | abcab\$ |
| 4 | 5 | b\$ |
| 5 | 2 | bcab\$ |
| 6 | 3 | cab\$ |

## Backward search

- The maximum interval prefixed with a string $w$ is called w-interval
- The process of computing cw-interval from w-interval for a character c is called backward search

| ab-interval $\{$ | SA position | SA | Sorted suffixes |
| :---: | :---: | :---: | :---: |
|  | 1 | 6 | \$ |
|  | 2 | 4 | ab\$ |
|  | 3 | 1 | abcab\$ |
| b-interval $\{$ | 4 | 5 | b\$ |
|  | 5 | 2 | bcab\$ |
|  | 6 | 3 | cab\$ |

- Can be conducted in $O(r)$ space ( $r$ is the number of the runs of BWT )

## Compute LZ77 phrases using backward search on RLBWT of $T$

- Suppose the next LZ77 phrase ends with $T[j]$
- Compute $T[i . . j]$-interval in decreasing order of $i=j, j-1, \ldots$
- If $T[i . . j]$-interval contains a SA-value greater than $i$, the phrase will continue to grow
- If not, encode the LZ77 phrase

## One-pass Algorithm [Nishimoto \& Tabei, 2019]

- One-pass algorithm can compute the text position of LZ77 phrase in a single pass while keeping track of two SA-positions and their SA-values per run

## One-pass Algorithm [Nishimoto \& Tabei, 2019]

- One-pass algorithm can compute the text position of LZ77 phrase in a single pass while keeping track of two SA-positions and their SA-values per run

## Two-pass Algorithm (First pass)

- In the first pass, we keep track of only SA-positions, which are enough to compute $\lambda_{h}$ and $c_{h}$ of LZ77 phrase ( $\pi_{h}, \lambda_{h}, \mathrm{c}_{h}$ ), and also compute the sequence $\mathrm{k}_{1}, \mathrm{k}_{2}, \ldots, \mathrm{k}_{z}$ of SA-positions such that $\mathrm{SA}\left[\mathrm{k}_{h}\right]=\pi_{h}$.
- By discarding SA-values, we can reduce the space by $2 r \lg n$ bits

## Two-pass Algorithm (Second pass)

- Build the rank data structure for a bit vector $V$ marking SA-positions
- While visiting SA-positions in the decreasing order of their SA-values, we check if the current SA-position is marked, and if so store the current SA-value (text position) at $P\left[\operatorname{rank}_{1}(V, i)\right]$
- Finally, we scan the sequence $\mathrm{k}_{1}, \mathrm{k}_{2}, \ldots, \mathrm{k}_{z}$ and output $\pi_{h}=P\left[\operatorname{rank}_{1}\left(V, \mathrm{k}_{h}\right)\right]$

Return the number of 1's in $V[1 . . \mathrm{i}]$

## Two-pass Algorithm (Second pass)

- $\pi_{h}=\mathrm{SA}\left[\mathrm{k}_{h}\right]$ can be computed in the second pass of retrieving

SA-positions for suffixes of $T$ from right to left order

$$
T=\square
$$

## Two-pass Algorithm (Second pass)

- $\pi_{h}=\mathrm{SA}\left[\mathrm{k}_{h}\right]$ can be computed in the second pass of retrieving SA-positions for suffixes of $T$ from right to left order
- The second pass can be conducted in parallel

We compared one-pass and two-pass algorithms on some highly-compressible texts

| dataset | Alphabet <br> size | Length of the <br> string | \#runs <br> in the BWT | \#LZ77 <br> phrases | -index <br> [KiB] |

|  |  | 8 | 7353 | 6855 | 498 | 1.061 |

## Conclusion

- We propose a two-pass algorithm and show by experiments that it works in $23 \%$ to $37 \%$ less space with up to $10 \%$ increase of computational time when we use 8 threads.
- The reduced space may be used to employ a space-consuming but faster $r$-index to improve the throughput if processing $3 G B$ text in 2 hours is too slow.
